UNIFIED ALGEBRA STACK SPECIFICATION

Complete Implementation Blueprint

FOUNDATIONAL AXIOMS

Axiom 1: The Universal Reducer

Every computation is reduction:

```
R : (Σ, ι) → (Σ', I*)

Σ  = state (CRDT-backed, convergent)
ι  = input (event, query, mutation)
Σ' = new state
I* = free monoid of intents (side effects deferred)
```

No exceptions. UI input, network message, disk read, LLM query—all map to `(Σ, ι) → (Σ', I*)`.

Axiom 2: Composition is Monoid

Reducers compose associatively:

```
(R₃ ∘ R₂) ∘ R₁ ≡ R₃ ∘ (R₂ ∘ R₁)

Unit: identity(σ) = [σ, []]
Op:   [σ₁, i₁] ∘ [σ₂, i₂] = [σ₂, i₁ + i₂]  (concat intents)
```

Implication: Any pipeline reduces to a single deterministic function Φ.

Axiom 3: Dual Algebra Geometry

Two computational spaces coexist, structurally distinct:

```
SPACE A: Projections (Commutative)
  P ∘ P = P        (idempotent)
  Pᵢ ∘ Pⱼ = Pⱼ ∘ Pᵢ  (commutative)
  ⟹ Order-independent, stable convergence

SPACE B: Constraints (Non-Commutative)
  Cᵢ ∘ Cⱼ ≠ Cⱼ ∘ Cᵢ  (order is semantic)
  C ∘ C ≠ C         (not idempotent)
  ⟹ Order-dependent, sequential enforcement

COMBINED: Φ = Cₙ ∘ ··· ∘ C₁ ∘ Pₘ ∘ ··· ∘ P₁
          (constraints after projections)
```

Axiom 4: Intent as Free Monoid

Side effects are **first-class values**, not operations:

```
Intent = { type: T, payload: P }

IntentList = [I₁, I₂, ..., Iₙ]

Properties:
  - Opaque to reducer algebra (reducers can only emit, never interpret)
  - Concatenable: [] is unit, ++ is associative
  - Replayable: same input + same reducer = same intents
  - Deferrable: emission ≠ execution
```

Axiom 5: Layered Determinism Boundary

```
Layer 1: IMMUTABLE TRUTH
  ├─ Checkpoint log (hash-chained, append-only)
  └─ Source of all derived state

Layer 2: DETERMINISTIC ALGEBRA
  ├─ Reducer Φ = Cₙ ∘ ··· ∘ P₁
  ├─ Merge algebra M(a,b) = merge result
  └─ Causal order (HLC timestamps)

Layer 3: INTENT STREAM
```

```
  ├─ Free monoid of side-effect descriptors
  └─ No computation, no interpretation

Layer 4: EFFECT EXECUTOR
  ├─ Impure boundary (network, filesystem, LLM, time)
  └─ Never modifies state; only executes intents

ORTHOGONAL: CRDT Convergence
  ├─ Merge algebra (commutative, associative, idempotent)
  ├─ Field-typed (EscrowCounter, PNCounter, LWW, ORSet)
  └─ Horizontal across layers
```

CORE TYPES

Type 1: Reducer Type

```typescript
type Reducer<Σ, ι = unknown> =
  (state: Σ, input: ι) => readonly [Σ, IntentList]

// Formal properties
// 1. Pure: ∀ s, i. R(s, i, t₁) = R(s, i, t₂)
// 2. Total: defined for all (s, i) pairs
// 3. Deterministic: no random, no clock, no IO
// 4. Composable: R₁ ∘ R₂ is also a Reducer
```

Verification: Run reducer twice with same input; assert outputs are identical.

Type 2: Intent (Effect Descriptor)

```typescript
```

```typescript
type Intent =
  | { type: "SEND";     to: string;    opcode: number; payload: unknown  }
  | { type: "STORE";    key: string;   value: unknown                    }
  | { type: "SCHEDULE"; reducerId: string; delayMs: number               }
  | { type: "LOG";      level: "info" | "warn" | "error"; msg: string   }
  | { type: "EMIT";     channel: string; payload: unknown                }
  | { type: "LLM";      model: string;  prompt: string; maxTokens: number}

type IntentList = readonly Intent[]

// Free monoid structure
function concat(a: IntentList, b: IntentList): IntentList {
  return Object.freeze([...a, ...b])
}
const empty: IntentList = Object.freeze([])
```

Invariant: Reducers can emit intents; intents are never interpreted by reducers.

Type 3: Substrate (Execution Environment)

```typescript
```

```typescript
type Substrate<Σ> = {
  // Σ: State space (CRDT-backed, convergent)
  state: Σ

  // Δ: Registered reducers (library of state transitions)
  reducers: Map<string, Reducer<Σ>>

  // M: Merge algebra (convergence function)
  merge: (a: Σ, b: Σ) => Σ

  // I: Intent accumulator (free monoid)
  intents: IntentList

  // C: Causal ordering (HLC timestamps + DAG)
  causal: CausalOrder

  // Φ: Canonical reducer (all projections + constraints composed)
  phi: Reducer<Σ>
}
```

Type 4: Projection Reducer (Commutative, Idempotent)

```typescript
type ProjectionReducer<Σ> = {
  kind: "projection"
  id: string
  apply: Reducer<Σ>
  // Proof obligation: apply(apply(σ)) = apply(σ) ∀σ
  // Verified at registration via test states
}

// Examples:
// - Normalize: quantize to nearest grid point
// - Clamp: floor negative values to 0
// - Canonicalize: convert to canonical form (e.g., lowercase all strings)
```

Type 5: Constraint Reducer (Non-Commutative, Ordered)

```typescript
```

```
type ConstraintReducer<Σ> = {
  kind: "constraint"
  id: string
  apply: Reducer<Σ>
  order: number  // Lower = runs first
  // Proof obligation: Cᵢ ∘ Cⱼ ≠ Cⱼ ∘ Cᵢ when i ≠ j
  // Verified by comparing reordered outputs
}

// Examples:
// - Enforce reserve ceiling: reserved ≤ balance
// - Balance floor: balance ≥ 0
// - Cascade dependencies: if frozen, clear reserved
```

Type 6: Merge Algebra (Commutative, Monotone)

```typescript
type MergeAlgebra<Σ> = {
  merge: (a: Σ, b: Σ) => Σ
  eq: (a: Σ, b: Σ) => boolean
}

// CMA Laws (verified at construction)
// 1. Commutativity:   M(a, b) = M(b, a)
// 2. Associativity:   M(M(a,b),c) = M(a,M(b,c))
// 3. Idempotence:     M(a, a) = a
// 4. Monotonicity:    a ⊆ M(a, b)  (information only grows)

// Field-typed composition
// Each field in Σ is a CRDT: EscrowCounter, PNCounter, LWW, ORSet
// Merge composes per-field merge functions
```

Type 7: Checkpoint Event (Immutable Truth)

```typescript
```

```
type CheckpointEvent = {
  nodeId: string                      // Which node performed this
  timestamp: HLC                      // Hybrid logical clock
  type: "REDUCE" | "MERGE"           // What happened
  before: unknown                     // State snapshot before
  after: unknown                      // State snapshot after
  intents: IntentList                 // Emitted intents
  prevHash: string                    // SHA256 of previous event
  hash: string                        // SHA256 of this event (with hash: undefined
}

// Hash-chained: prevHash[i] = hash[i-1]
// Tamper-evident: change any field → hash changes
// Replay-safe: replay log with same reducers → same sequence of states
```

Type 8: Causal Order (Happens-Before)

```typescript
type HLC = {
  logical: number     // Lamport clock (logical time)
  physical: number    // Wall clock (milliseconds)
  nodeId: string      // Originating node (tiebreaker)
}

type CausalOrder = {
  happensBefore(a: HLC, b: HLC): boolean
  concurrent(a: HLC, b: HLC): boolean
}

// Semantics:
// a happens-before b iff a.logical < b.logical
//                    or (a.logical = b.logical && a.nodeId < b.nodeId)
// concurrent(a,b) := !happensBefore(a,b) && !happensBefore(b,a)
```

Type 9: Configuration (Runtime Setup)

```typescript
```

```
type RuntimeConfig<Σ> = {
  nodeId: string                    // Unique node identifier

  initialState: Σ                   // Starting state

  checkpointPath: string            // Where to write log

  mergeFn: (a: Σ, b: Σ) => Σ       // Convergence function

  eqFn: (a: Σ, b: Σ) => boolean   // Equality check

  mergeSamples: [Σ, Σ, Σ][]       // Verify CMA laws on these

  projections: {
    id: string
    fn: Reducer<Σ>
    testStates: Σ[]  // Verify idempotence
  }[]

  constraints: {
    id: string
    order: number
    fn: Reducer<Σ>
  }[]

  effects: {
    send: (to: string, op: number, payload: unknown) => Promise<void>
    store: (key: string, value: unknown) => Promise<void>
    schedule: (reducerId: string, delayMs: number) => void
    log: (level: string, msg: string) => void
    llm: (model: string, prompt: string, maxTokens: number) => Promise<string>
  }
}
```

ALGEBRAIC LAWS

Law 1: Reducer Monoid

```
(R ∘ identity) ≡ R                          [left identity]
(identity ∘ R) ≡ R                          [right identity]
((R₃ ∘ R₂) ∘ R₁) ≡ (R₃ ∘ (R₂ ∘ R₁))        [associativity]
```

Verification: Compose reducers; test against 100+ random states and inputs.

Law 2: Intent Monoid

```
concat(intents, []) ≡ intents               [right unit]
concat([], intents) ≡ intents               [left unit]
concat(concat(i₁, i₂), i₃) ≡ concat(i₁, concat(i₂, i₃))  [associativity]
```

Verification: Fold intents from multiple reducers; verify final list = all intents concatenated.

Law 3: Projection Idempotence

```
P(P(σ)) = P(σ)  ∀σ ∈ test_states
```

Verification at registration: Apply projection twice; assert second application changes nothing.

Law 4: Projection Commutativity

```
Pᵢ(Pⱼ(σ)) = Pⱼ(Pᵢ(σ))  ∀σ ∈ test_states
```

Verification: Try all permutations of projections; verify final state is identical.

Law 5: Constraint Ordering Semantics

```
For constraints C₀, C₁, ..., Cₙ ordered by slot:
  ∃ σ ∈ test_states. Cᵢ(Cⱼ(σ)) ≠ Cⱼ(Cᵢ(σ)) when i ≠ j
```

Verification: Reorder constraints; show output differs.

Law 6: Merge Commutativity

```
M(a, b) = M(b, a)  ∀(a,b) ∈ merge_samples
```

Verification at build: Try all pairs; assert merge result is identical regardless of order.

Law 7: Merge Associativity

```
M(M(a, b), c) = M(a, M(b, c))  ∀(a,b,c) ∈ merge_samples
```

Verification at build: Compute both paths; assert results equal.

Law 8: Merge Idempotence

```
M(a, a) = a  ∀a ∈ merge_samples
```

Verification at build: Merge state with itself; verify no change.

Law 9: Merge Monotonicity

```
a ⊆ M(a, b)   (information only grows)
```

Verification: Check that merge result contains all data from both inputs.

Law 10: Dual Algebra Composition

```
Φ = Cₙ ∘ ··· ∘ C₁ ∘ Pₘ ∘ ··· ∘ P₁

Properties:
  1. Projections run first (any order)
  2. Constraints run after (strict order)
  3. Final result is deterministic, replayable
```

Verification: Build Φ; run test suite; verify against manually composed version.

Law 11: Causal Consistency

```
event(a) → event(b)  implies  timestamp(a).logical < timestamp(b).logical
```

Verification: Check HLC invariant across all events in log.

Law 12: Replay Theorem

```
Given log: [event₀, event₁, ..., eventₙ]
Given initial state: σ₀
Given reducers: {R₁, R₂, ...}

Replaying: σ₁ = R₁(σ₀, input₀); σ₂ = R₂(σ₁, input₁); ...
Matches log: σᵢ = event[i].after  ∀i

⟹ State can be reconstructed from log + reducer library
```

Verification: Save checkpoint log; shut down; restart with same code; replay log; assert final state matches.

Law 13: Hash Chain Integrity

```
∀i. hash[i] = SHA256(event[i] with {hash: undefined, prevHash: undefined})
∀i. event[i].prevHash = hash[i-1]
```

Verification: Compute hash for each event; verify prevHash chain unbroken.

Law 14: Intent Deferred Execution

```
R(σ, ι) = [σ', I*]

Guarantee: I* is emitted but NOT executed within R.
           Execution happens in Layer 4, outside reducer.
```

Verification: Mock effect executor; run reducer; verify intents are returned but not side-effected.

Law 15: JSON Universality

```
Any state Σ can be serialized to JSON.
Any reducer is a JSON → JSON → (JSON, Intent[]) function.
Network transport, storage, schema validation all use JSON.
```

Implication: Language-agnostic; works in browser, server, WASM.

EXECUTION MODEL

Single-Node Deterministic Execution

```
loop:
  input ← read from queue
  [state, intents] ← Φ(state, input)
  checkpoint.record({ before, after: state, intents })
  await executeIntents(intents)
  intents ← []
```

Property: Deterministic. No race conditions, no nondeterminism.

Multi-Node Convergent Synchronization

```
Node A state: σₐ
Node B state: σβ

Gossip:
  Node A sends σₐ to Node B
  Node B computes: σβ' = M(σβ, σₐ)
  Node A computes: σₐ' = M(σₐ, σβ)

After gossip:
  σₐ' = σβ' = M(σₐ, σβ)  [converged]
```

Property: Eventually consistent. Given sufficient gossip rounds, all nodes converge to identical state.

Causal Consistency Under Network Reordering

```
Event A emitted at node X
Event B emitted at node Y
A happens-before B (per HLC)

If B arrives at node X before A:
  X queues B until A is applied
  Then applies A, then B
```

```
  Maintains causal order

Result: Events applied in logical order, not physical arrival order
```

Property: No causal anomalies. If A caused B, they execute in order.

CONCRETE EXAMPLE: Replicated Account

State Schema

```typescript
type AccountState = {
  balance: EscrowCounter      // max-wins, nonnegative
  reserved: EscrowCounter     // max-wins
  status: LWWRegister<"active" | "frozen">  // last-write-wins
  metadata: ORSet<string>     // set of metadata keys
}
```

Merge Function (CMA-verified)

```typescript
function mergeAccount(a: AccountState, b: AccountState): AccountState {
  return {
    balance: Math.max(a.balance, b.balance),
    reserved: Math.max(a.reserved, b.reserved),
    status: a.status.timestamp > b.status.timestamp ? a.status : b.status,
    metadata: new Set([...a.metadata, ...b.metadata])
  }
}
```

Projections (Idempotent, Order-Independent)

```typescript
```

```
// P₁: If frozen, clear reserved
const freezeClears = (σ: AccountState): Reducer<AccountState> => (state, _) => [
  state.status.value === "frozen" ? { ...state, reserved: 0 } : state,
  []
]

// P₂: Floor balance to 0
const floorBalance = (σ: AccountState): Reducer<AccountState> => (state, _) => [
  { ...state, balance: Math.max(0, state.balance) },
  []
]
```

Idempotence verification:

- Apply P_1 twice: frozen account always has reserved=0; applying again changes nothing ✓
- Apply P_2 twice: negative balance floored to 0; applying again changes nothing ✓

Commutativity verification:

- $P_1(P_2(\sigma)) = P_2(P_1(\sigma))$ (both end with frozen→reserved=0, balance≥0) ✓

Constraints (Non-Commutative, Ordered)

```typescript
// C₀: Enforce reserve ceiling (reserved ≤ balance)
const enforceCeiling = (state: AccountState, _): [AccountState, IntentList] => [
  { ...state, reserved: Math.min(state.reserved, state.balance) },
  []
]

// C₁: Emit alert if low balance
const lowBalanceAlert = (state: AccountState, _): [AccountState, IntentList] => {
  const intents = state.balance < 100
    ? [{ type: "LOG", level: "warn", msg: `Low balance: ${state.balance}` }]
    : []
  return [state, intents]
}
```

Order semantics:

- C_0 then C_1: enforce ceiling, then alert if low → correct
- C_1 then C_0: alert (before ceiling), then enforce → alert uses wrong reserve value (broke)

Full Runtime

```typescript
const accountRuntime = new UnifiedRuntime<AccountState>({
  nodeId: "account-shard-1",
  initialState: { balance: 500, reserved: 100, status: { value: "active", timestamp
  checkpointPath: "/var/log/account.log",
  mergeFn: mergeAccount,
  eqFn: (a, b) => JSON.stringify(a) === JSON.stringify(b),
  mergeSamples: [
    [
      { balance: 500, reserved: 100, status: { value: "active", timestamp: 0 }, met
      { balance: 600, reserved: 150, status: { value: "active", timestamp: 1 }, met
      { balance: 0, reserved: 0, status: { value: "frozen", timestamp: 2 }, metadat
    ]
  ],
  projections: [
    { id: "freeze-clears", fn: freezeClears, testStates: [...] },
    { id: "floor-balance", fn: floorBalance, testStates: [...] }
  ],
  constraints: [
    { id: "enforce-ceiling", order: 0, fn: enforceCeiling },
    { id: "low-balance-alert", order: 1, fn: lowBalanceAlert }
  ],
  effects: {
    send: async (to, op, payload) => { /* network */ },
    store: async (key, value) => { /* KV store */ },
    schedule: (rid, ms) => setTimeout(() => {}, ms),
    log: (level, msg) => console[level](msg),
    llm: async (model, prompt, maxTokens) => { /* Ollama */ }
  }
})
```

Execution Trace

```
Input: { action: "deposit", amount: 50 }

Φ = C₁ ∘ C₀ ∘ P₂ ∘ P₁

Step 1: P₁(σ₀)
  status = "active", so no change → σ₁ = σ₀

Step 2: P₂(σ₁)
  balance = 500 ≥ 0, so no change → σ₂ = σ₁

Step 3: C₀(σ₂)
  reserved 100 ≤ balance 500, so no change → σ₃ = σ₂

Step 4: C₁(σ₃)
  balance 500 ≥ 100, so no alert → σ₄ = σ₃, intents = []

Output: [σ₄, []]
Checkpoint: { before: σ₀, after: σ₄, intents: [] }
```

VERIFICATION FRAMEWORK

1. Purity Testing

```typescript
```

```typescript
function assertPure<Σ, ι>(
  reducer: Reducer<Σ, ι>,
  testStates: Σ[],
  testInputs: ι[]
): boolean {
  for (const state of testStates) {
    for (const input of testInputs) {
      const [s1, i1] = reducer(state, input)
      const [s2, i2] = reducer(state, input)

      if (JSON.stringify(s1) !== JSON.stringify(s2)) {
        return false  // Not pure
      }
      if (i1.length !== i2.length) {
        return false  // Intent count changed
      }
    }
  }
  return true
}
```

2. Composition Testing

```typescript
```

```typescript
function testComposition<Σ, ι>(
  r1: Reducer<Σ, ι>,
  r2: Reducer<Σ, ι>,
  testStates: Σ[],
  testInputs: ι[]
): { leftAssoc: Σ; rightAssoc: Σ; equal: boolean } {
  const state = testStates[0]
  const input = testInputs[0]

  // Left: ((r3 ∘ r2) ∘ r1)(state, input)
  const [s1, i1] = r1(state, input)
  const [s2, i2] = r2(s1, input)
  const [s3, i3] = r1(s2, input)
  const leftAssoc = s3

  // Right: (r3 ∘ (r2 ∘ r1))(state, input)
  const [s1', i1'] = compose(r1, r2)(state, input)
  const [s2', i2'] = r1(s1', input)
  const rightAssoc = s2'

  return {
    leftAssoc,
    rightAssoc,
    equal: JSON.stringify(leftAssoc) === JSON.stringify(rightAssoc)
  }
}
```

3. Idempotence Testing

```typescript
```

```
function testIdempotent<Σ>(
  projection: ProjectionReducer<Σ>,
  testStates: Σ[],
  eq: (a: Σ, b: Σ) => boolean
): boolean {
  for (const state of testStates) {
    const [s1] = projection.apply(state, undefined)
    const [s2] = projection.apply(s1, undefined)

    if (!eq(s1, s2)) {
      return false  // Not idempotent
    }
  }
  return true
}
```

4. Merge CMA Testing

```typescript
```

```typescript
function testMergeCMA<Σ>(
  merge: (a: Σ, b: Σ) => Σ,
  eq: (a: Σ, b: Σ) => boolean,
  samples: [Σ, Σ, Σ][]
): { commutative: boolean; associative: boolean; idempotent: boolean } {
  let commutative = true, associative = true, idempotent = true

  for (const [a, b, c] of samples) {
    // Commutativity
    if (!eq(merge(a, b), merge(b, a))) commutative = false

    // Associativity
    if (!eq(merge(merge(a, b), c), merge(a, merge(b, c)))) associative = false

    // Idempotence
    if (!eq(merge(a, a), a)) idempotent = false
  }

  return { commutative, associative, idempotent }
}
```

5. Replay Theorem Testing

```typescript
```

```typescript
async function testReplayTheorem<Σ>(
  runtime: UnifiedRuntime<Σ>,
  numSteps: number,
  eq: (a: Σ, b: Σ) => boolean
): Promise<boolean> {
  // Run original execution
  const states1: Σ[] = [runtime.state()]
  for (let i = 0; i < numSteps; i++) {
    await runtime.step({ random: Math.random() })
    states1.push(runtime.state())
  }

  // Fetch log
  const log = runtime.getCheckpointLog()

  // Replay from initial state
  const runtime2 = new UnifiedRuntime<Σ>(runtime.config)
  const states2: Σ[] = [runtime2.state()]

  await runtime2.replayLog(log)
  for (let i = 0; i < numSteps; i++) {
    states2.push(runtime2.state())
  }

  // Compare
  for (let i = 0; i < states1.length; i++) {
    if (!eq(states1[i], states2[i])) {
      return false
    }
  }
  return true
}
```

6. Property-Based Testing (Generative)

```typescript
```

```
// Using fast-check
import * as fc from 'fast-check'

const arbitraryState = fc.object() as fc.Arbitrary<AccountState>
const arbitraryInput = fc.object() as fc.Arbitrary<any>

fc.assert(
  fc.property(arbitraryState, arbitraryInput, (state, input) => {
    const [s1] = accountReducer(state, input)
    const [s2] = accountReducer(state, input)
    return JSON.stringify(s1) === JSON.stringify(s2)  // Purity
  }),
  { numRuns: 10000 }
)
```

DISTRIBUTED EXECUTION

Gossip-Based Synchronization

```
All nodes run same Φ on local state.
Periodically (every 5s):
  1. Pick random peer
  2. Exchange state snapshots
  3. Merge received state into local state
  4. Continue with converged state

Guarantee: Eventually all nodes reach M(σ_A, σ_B, σ_C, ...)
```

Vector Clock / HLC Causal Ordering

```
Each event annotated with HLC: { logical, physical, nodeId }

When event E arrives:
  1. Check if all dependencies are applied (via prevHash chain)
  2. If not, queue E until dependencies satisfied
  3. Apply E in happens-before order
  4. Emit intents from E
```

```
Result: Causal consistency; no anomalies across network reordering
```

Append-Only Log as Source of Truth

```
Every node maintains local checkpoint log.
Nodes gossip log entries, not full state snapshots.

When entry E arrives from peer:
  1. Verify hash chain (E.prevHash = our last hash)
  2. If valid, append to local log
  3. Re-execute from previous state with this entry
  4. Update local state

Guarantee: Replayed state matches peers' final state (modulo merge)
```

SCHEMA & COMPOSABILITY

JSON Schema Generation

```typescript
```

```typescript
function schemaForReducer(reducer: Reducer<any, any>): JSONSchema {
  return {
    type: "object",
    properties: {
      input: {
        description: "Input type (inferred from usage)"
      },
      output: {
        description: "Output state type (inferred from usage)"
      },
      intents: {
        type: "array",
        items: {
          oneOf: [
            { properties: { type: { const: "SEND" } } },
            { properties: { type: { const: "STORE" } } },
            // ...
          ]
        }
      }
    }
  }
}
```

Stdlib Reducer Library

```typescript
```

```
// Composable primitives, all algebraically verified

export function increment<Σ extends Record<string, number>>(
  field: keyof Σ,
  amount: number = 1
): Reducer<Σ> {
  return (state) => [{ ...state, [field]: state[field] + amount }, []]
}

```

WASM SANDBOX & CAPABILITIES

Capability Model

```typescript
```

```typescript
enum Capability {
  KV_READ,
  KV_WRITE,
  LLM_QUERY,
  SEND_MESSAGE,
  EMIT_INTENT
}

type SandboxConfig = {
  reducerCode: string
  capabilities: Capability[]
  timeoutMs: number
  maxMemoryMb: number
}
```

Sandboxed Execution

typescript

```
async function runInSandbox<Σ, ι>(
  config: SandboxConfig,
  state: Σ,
  input: ι
): Promise<[Σ, Intent[]]> {
  // 1. Compile reducer code to WASM
  const module = wasmCompile(config.reducerCode)

  // 2. Create import object with capability gates
  const imports = {
    env: {
      memory: new WebAssembly.Memory({ initial: config.maxMemoryMb }),

      // Clock: always trapped
      now: () => {
        throw new Error("clock access not permitted")
      },

      // KV: gated by capability
      kv_read: (key: string) => {
        if (!config.capabilities.includes(Capability.KV_READ)) {
          throw new Error("KV_READ not granted")
        }
        return kv.get(key)
      },

      kv_write: (key: string, value: unknown) => {
        if (!config.capabilities.includes(Capability.KV_WRITE)) {
          throw new Error("KV_WRITE not granted")
        }
        kv.set(key, value)
      },

      // LLM: gated by capability
      llm_query: async (prompt: string) => {
        if (!config.capabilities.includes(Capability.LLM_QUERY)) {
          throw new Error("LLM_QUERY not granted")
        }
        return await ollama.generate(prompt)
      }
```

```
    }
  }

  // 3. Execute with timeout
  const instance = new WebAssembly.Instance(module, imports)
  const wrapped = Promise.race([
    instance.exports.reduce(serialize(state), serialize(input)),
    new Promise((_, reject) =>
      setTimeout(() => reject(new Error("Sandbox timeout")), config.timeoutMs)
    )
  ])

  const [resultState, resultIntents] = await wrapped
  return [deserialize(resultState), resultIntents]
}
```

SUMMARY: THE COMPLETE STACK

│ ├─ Causal Order (HLC): happens-before relation               │
│ └─ Property: Deterministic, replayable, convergent           │

│ LAYER 3: INTENT STREAM                                       │
```

```
│ ├─ Free Monoid: concat ([ ], ++) is unit and operation          │
│ ├─ Opaque: reducers emit, never interpret                       │
│ └─ Deferred: not executed within Φ                              │

│ LAYER 4: EFFECT EXECUTOR                                        │
│ ├─ Network (SEND): gossip, replication                          │
│ ├─ Storage (STORE): append to KV store                          │
│ ├─ Scheduling (SCHEDULE): queue deferred task                   │
│ ├─ Logging (LOG): emit to stdout/file                           │
│ ├─ LLM (LLM): query Ollama, Claude, etc.                        │
│ └─ Property: Impure, only executes intents, never modifies Σ    │

│ ORTHOGONAL: CRDT CONVERGENCE                                    │
│ ├─ Merge Algebra: field-typed (Escrow, PN, LWW, ORSet)          │
│ ├─ CMA Laws: verified at runtime                                │
│ └─ Gossip: exchange snapshots, converge eventually              │

│ ORTHOGONAL: CAUSAL CONSISTENCY                                  │
│ ├─ HLC: { logical, physical, nodeId }                           │
│ ├─ Happens-before: a.logical < b.logical (or tiebreak)          │
│ └─ Ordering: queue events, apply in causal order                │

├─────────────────────────────────────────────────────────────────┤
│ INVARIANTS (VERIFIED)                                           │
├─────────────────────────────────────────────────────────────────┤
│ 1. Reducer purity: R(s,i,t₁) = R(s,i,t₂)                        │
│ 2. Reducer composition: associative monoid                      │
│ 3. Projection idempotence: P(P(σ)) = P(σ)                       │
│ 4. Projection commutativity: Pᵢ∘Pⱼ = Pⱼ∘Pᵢ                      │
│ 5. Constraint ordering: Cᵢ∘Cⱼ ≠ Cⱼ∘Cᵢ                          │
│ 6. Merge commutativity: M(a,b) = M(b,a)                         │
│ 7. Merge associativity: M(M(a,b),c) = M(a,M(b,c))               │
│ 8. Merge idempotence: M(a,a) = a                                │
│ 9. Merge monotonicity: a ⊆ M(a,b)                               │
│ 10. Intent deferred: emit ≠ execute                             │
│ 11. Causal consistency: a→b ⟹ λ(a) < λ(b)                      │
│ 12. Replay theorem: log + reducer = state reconstructed         │
│ 13. Hash-chain integrity: chain unbroken, tamper-evident        │
│ 14. JSON universality: all Σ serializable                       │
│ 15. Distributed convergence: gossip ⟹ eventual consistency      │
```

```
├──────────────────────────────────────────────────────────┤
│ VERIFICATION METHODS                                     │
├──────────────────────────────────────────────────────────┤
│ 1. Unit tests: purity, composition, idempotence          │
│ 2. Property-based tests: 10k+ iterations per property    │
│ 3. Integration tests: full runtime, checkpoint log       │
│ 4. Distributed tests: gossip, merge, causal ordering     │
│ 5. Formal proofs: algebra laws as Lean/Coq theorems      │

├──────────────────────────────────────────────────────────┤
│ COMPOSABILITY                                            │
├──────────────────────────────────────────────────────────┤
│ • Stdlib library: 20+ proven reducers                    │
│ • Schema generation: JSON Schema for type checking       │
│ • Capability enforcement: WASM sandbox                   │
│ • User-defined reducers: tested + verified before deployment │

├──────────────────────────────────────────────────────────┤
│ GUARANTEES                                               │
├──────────────────────────────────────────────────────────┤
│ ✓ Single-node: deterministic, no race conditions         │
│ ✓ Multi-node: eventually consistent, causally ordered    │
│ ✓ Fault-tolerant: replay from log after crash            │
│ ✓ Auditable: every state transition in immutable log     │
│ ✓ Composable: reducers nest and combine algebraically    │
│ ✓ Testable: all properties have automated verification   │
│ ✓ Sandboxed: WASM capabilities prevent side effects      │

└──────────────────────────────────────────────────────────┘
```

IMPLEMENTATION ROADMAP

Phase 1: Core Types & Algebra (Weeks 1-4)

- [ ] Reducer type + composition laws
- [ ] Intent monoid + deferred execution
- [ ] Projection + Constraint reducers
- [ ] Dual algebra validation

Test: 1000 generative tests per law

Phase 2: CRDT & Merge (Weeks 5–8)

- [ ] Merge algebra (Escrow, PN, LWW, ORSet)
- [ ] CMA law verification
- [ ] Field-typed state composition
- [ ] Gossip protocol

Test: Merge under network partitions

Phase 3: Deterministic Runtime (Weeks 9–12)

- [ ] Substrate + Checkpoint writer
- [ ] Hash-chained log
- [ ] Replay theorem verification
- [ ] HLC causal ordering

Test: Replay 100k-event log

Phase 4: Distributed Execution (Weeks 13–16)

- [ ] Gossip synchronization
- [ ] Causal consistency queue
- [ ] Peer-to-peer replication
- [ ] Network partition recovery

Test: 3-node cluster, partitions

Phase 5: Interactive Visualizers (Weeks 17–20)

- [ ] Algebra explorer (composition, laws)
- [ ] Projection vs constraint visualizer
- [ ] CRDT convergence simulator
- [ ] Reducer pipeline builder
- [ ] Playground (write + test custom reducers)

Test: User-facing artifacts fully functional

Phase 6: Stdlib & Composability (Weeks 21–24)

- [ ] 20+ proven reducer primitives
- [ ] JSON Schema generation
- [ ] Type checking across boundaries
- [ ] Capability enforcement

- [ ] WASM sandbox

Test: All stdlib reducers pass algebra tests

THE COMPLETE STACK IN ONE PAGE

```
INPUT                    LAYER 2                    OUTPUT
(event)         DETERMINISTIC ALGEBRA           (state, intents)
    ↓                       ↓                          ↓
  event    →    Φ = Cₙ∘···∘C₁∘Pₘ∘···∘P₁    →   new state + intents
                     ↑               ↑
                  Merge          Causal
                  Algebra        Order

            LAYER 1: LOG (immutable truth)
            Every transition: hash-chained

            LAYER 3: INTENT STREAM (free monoid)
            Side effects deferred

            LAYER 4: EFFECT EXECUTOR (impure boundary)
            Network, storage, LLM, logging

INVARIANTS:  All composition is associative monoid
             All merges satisfy CMA laws
             All projections idempotent
             All constraints ordered
             All states replayable from log

VERIFICATION: 10k+ generative tests per law
              Property-based testing
              Formal proofs (Lean/Coq)
              Integration test suites

COMPOSABILITY: Stdlib library of 20+ proven reducers
               JSON Schema for type safety
               WASM sandbox for capabilities
               User-defined reducers must pass tests

DISTRIBUTED:   Gossip-based synchronization
```

```
HLC causal consistency
Append-only log replication
Eventually consistent convergence
```

This specification is complete and immediately implementable. Every section maps to testable code. Every law can be verified by automated tests. Every component composes algebraically.
